

# The Risks of Risk Management

---

James Pomeroy

October 2025

# Background

Why the interest?

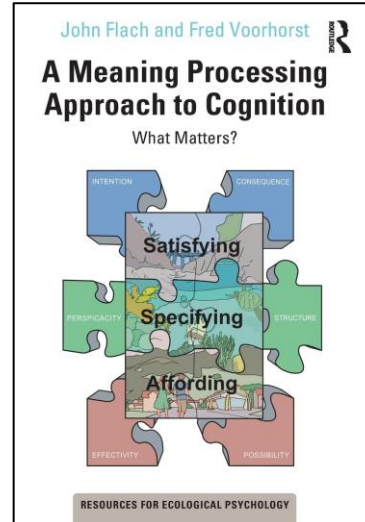

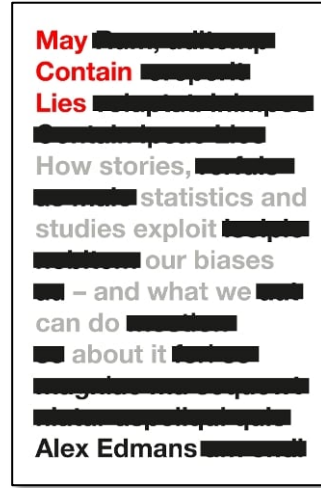

# Questions, doubts and uncertainties

# Thinkers who've shaped my views

# I will argue...

We're often working in complex situations that we don't recognize

Risk management tools are far more subjective than we ever want to acknowledge

The artifacts of risk management frequently create a false sense of security

There is much more we don't know or understand than we admit

Too often, plans are created in stable and predictable contexts, and focus on the routine

We downplay the power of rhetoric – words do indeed create the worlds that we work in

Step 1.

# Hazard Identification

# Hazard Identification

What happened yesterday  
shapes what hazards we  
identify today

We identify hazards using  
individual constructed  
categories, but they often  
materialize synergistically

We identify what are  
familiar with - the known  
knowns

Safety is understood through representations of work such as audits, metrics, targets, management systems, strategies, theoretical models, awards, risk assessments, etc.

**The Reality-Representation Gap**

Safety is understood through the reality of work, such as time pressure, breakdowns, resources, fatigue, the environment, change, social life, etc.

Supervisor

Worker

The greater the distance from the reality of work, the more safety is understood through representations. We need representations to simplify the complexity of work, but like mirages in the desert, they can deceive us into believing that they are reality.

Step 2.

## Assessing the Risks

# Assessing the Risks

The McNamara Fallacy, placing trust in numbers above all else, including experience

Risks vs. scenarios. Most organisations had identified a pandemic was due, but no one predicted how the scenario would unfold

Step 3.

## Managing the Risks

# Managing the Risks

The paradox of planning: Mindlessness or mindful anticipation of the unexpected

The presumption that ever-greater controls leads to increased safety. Complexity often increases structural vulnerability

Plans are often created in stable conditions and carry many assumptions and biases

**False Assurance is a  
common theme found in  
many disasters**

When the metrics are green,  
the incidents are lean, and the  
audits are clean.

Step 4.

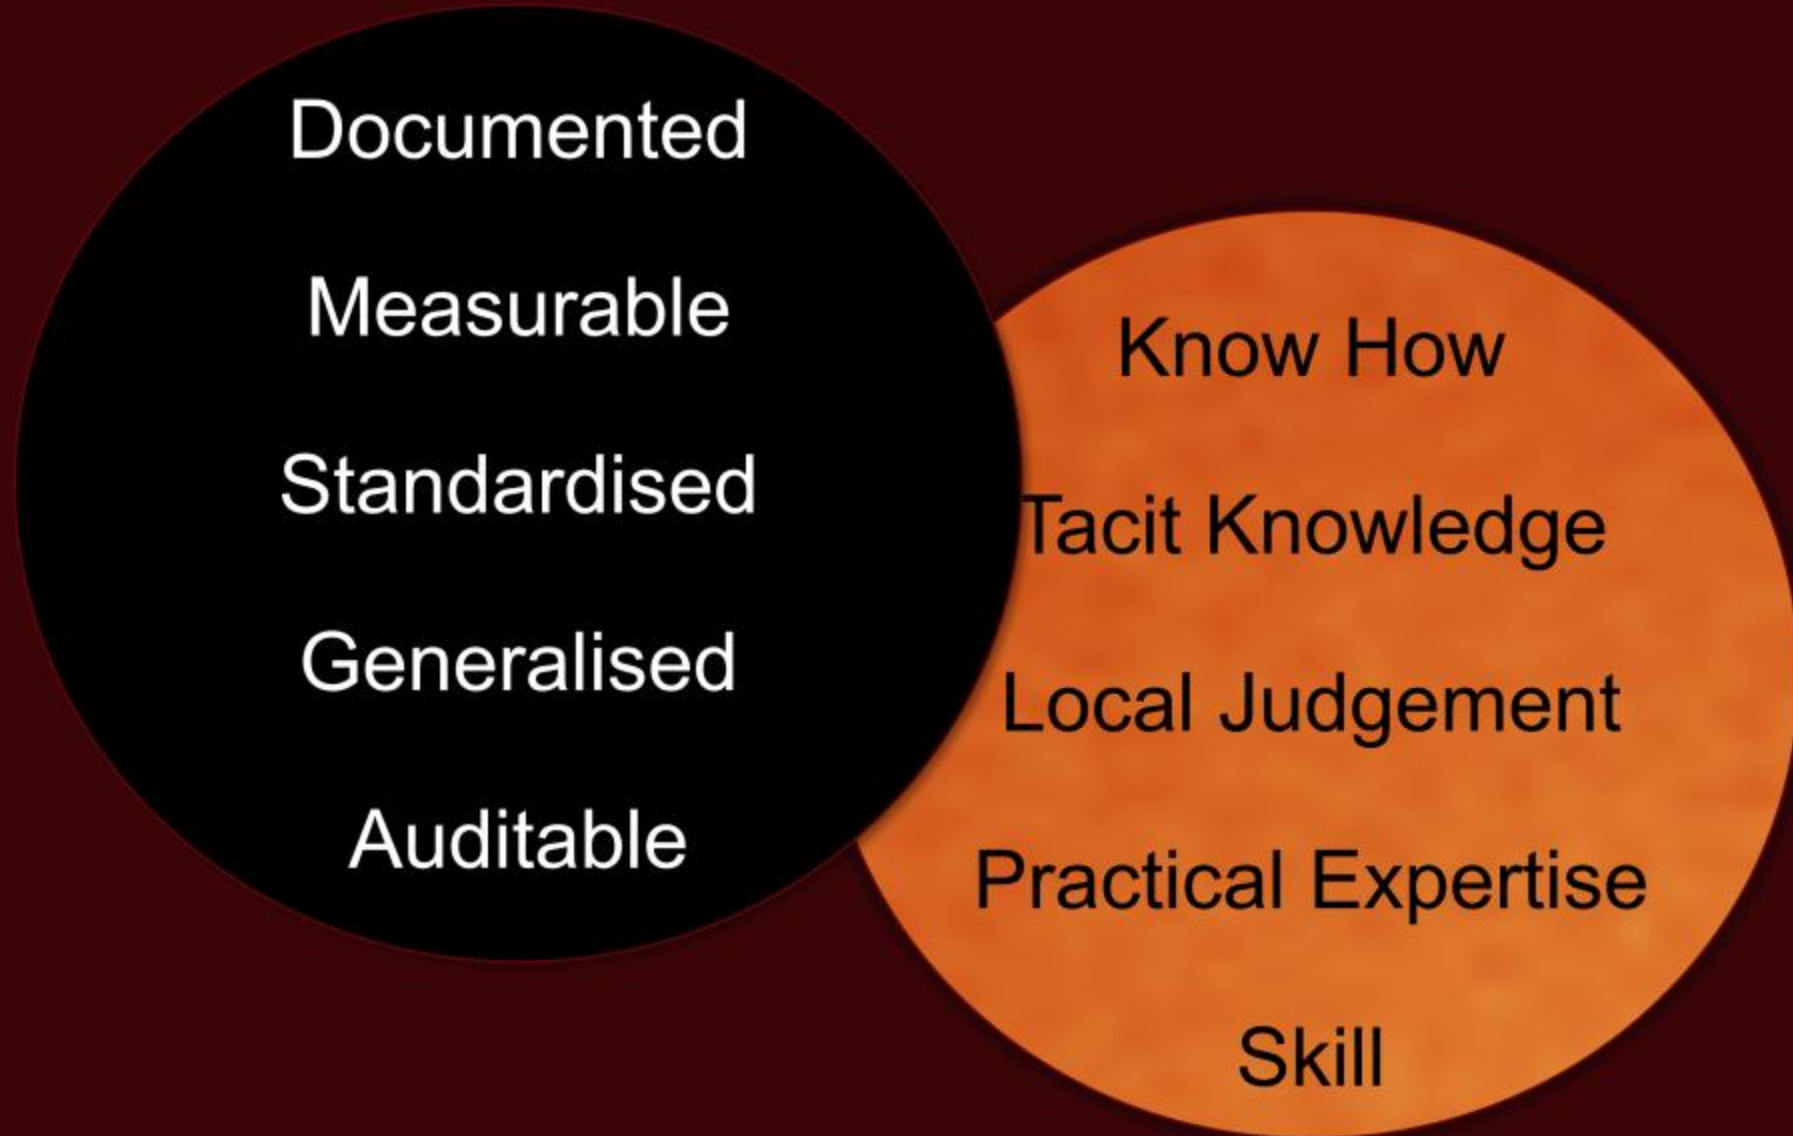

# Ensuring Competency

# Knowledge Displacement

When formalised knowledge eclipses local expertise and know how

# Six Takeaways

1-3

## Scenarios vs. risks and categories

Significant incidents rarely involve individual risks; assumed controls frequently fail.

## Agility vs. rigidity

Focus on agility, and the ability to diagnose and adapt to the circumstances.

## Tacit knowledge vs. models and metrics

Be alert to the biases of measurement and the dismissal of experience

# Six Takeaways

4-6

## Ensure strong feedback

The 'secret sauce' of aviation safety is recursive practice – learning from in-service experience

## Plans vs. realities

Be alert to potential delusion of plans. Focus on the realities that workers must address.

## Additional safety controls ≠ 100% safer

Greater safety measures can increase complexity and vulnerability

“

**We should reject ‘mechanical strategies’ that seek to identify, quantify and prioritise risks, but rather enable managers to understand and make sense of situations, so they are alert to respond and adapt to emergent problems.**

”
